

- carbon dioxide is excreted through the lungs
- kidneys excrete urea & excess water and ions

- kidney = two bean-shaped organs that filter the blood
- ureter = tube connecting the kidney to the bladder
- bladder = organ that stores urine, produced by kidney
- urethra = tube that connects the bladder to exterior

- the glomerulus (knot of capillaries), filters water, glucose, urea & ions from blood
- the nephron reabsorbs all of the glucose, some of the ions and most of the water, back into the blood
- urine is formed from: the urea, excess water and excess ions.

* the liver assimilates amino acids by converting them to proteins

↳ assimilation = uptake/use of nutrients by cells

↳ urea is formed in the liver from excess amino acids

↳ deamination is the removal of the nitrogen-containing part of amino acids to form urea

* excretion is important because it gets rid of toxic and excess substances.

Toxic consequences of high urea levels ::

- cell death
- reduced response to insulin → diabetes
- deposits inside blood vessels
